1 Notations

- $\hat{\mathbf{x}} = (\hat{x}_1, \hat{p}_1, \dots, \hat{x}_n, \hat{p}_n)^T$, vector of cannonical operators.
- $\Omega = \bigoplus_{j=1}^n \Omega_1$, where $\Omega_1 = \begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix}$. Note that, for n = 1, $[\hat{x}_i, \hat{x}_j] = i[\Omega_1]_{ij}$. Compactly,

$$[\hat{\mathbf{x}}, \hat{\mathbf{x}}^T] = i\Omega,$$
 (Canonical Commutation Relation)

where, think the commutation relation as element wise commutator.

- Borrowing from the optical and field-theoretical terminologies, canonical degrees of freedom are also referred to as 'modes'.
- $\hat{a}_j = \frac{\hat{x}_j + \hat{p}_j}{\sqrt{2}}$, annihilation operator.
- BCH formula: $e^{A+B} = e^A e^B e^{-\frac{1}{2}[A,B]}$ for operators A,B if [A,[A,B]] = [B,[B,A]] = 0

2 Gaussian States

2.1 Quadratic Hamiltonian and Gaussian States

The most general quadratic/second-order hamiltonian can be written as follows.

$$\hat{H} = \frac{1}{2}\hat{\mathbf{x}}^T H \hat{\mathbf{x}} + \hat{\mathbf{x}}^T \xi. \tag{1}$$

Here, ξ is a 2n-dimensional real vector. H is a $2n \times 2n$ symmetric matrix called Hamiltonian matrix, not to be confused with Hamiltonian. It can alsways be taken as a symmetric matrix because, the antisymmetric part with give a term proportional to identity matrix due to \mathbf{CCR} , which can always be discarded. If we take $\bar{\xi} = H^{-1}\xi$, then $\hat{H}' = \frac{1}{2}(\hat{\mathbf{x}} - \bar{\xi})^T H(\hat{\mathbf{x}} - \bar{\xi})$ is equivalent to \hat{H} up to some additive constant term.

Definition 1 (Gaussian State). Gaussian states are defined as all the ground and thermal states of second-order Hamiltonians [eq.1] with positive definite Hamiltonian matrix H > 0.

Thus a Gaussian state can be written as,

$$\rho_G = \frac{e^{-\beta \hat{H}}}{\text{Tr} \left[e^{-\beta \hat{H}} \right]},\tag{2}$$

where, $\beta > 0$ and \hat{H} is defined in Eq. 1. Ground state is the limiting value,

$$\rho_G = \lim_{\beta \to \infty} \frac{e^{-\beta \hat{H}}}{\operatorname{Tr}\left[e^{-\beta \hat{H}}\right]}.$$
 (3)

Note:

- All Gaussian states are mixed state by construction, except for the ground state.
- Gaussian states are parametrized by β , ξ and H. Though β is redundant and can be absorbed into H, it allows one to single out pure Gausian states as a limiting case like in Eq. 3.

2.2 Displacement operators

Definition 2 (Weyl operators).

$$\hat{D}_{\xi} = e^{i\xi^T \Omega \hat{\boldsymbol{x}}} = e^{i(\hat{x}_1 \xi_2 - \hat{p}_1 \xi_2)} \otimes \dots \otimes e^{i(\hat{x}_n \xi_{2n} - \hat{p}_n \xi_{2n-1})}, \tag{4}$$

where, $\xi \in \mathbb{R}^{2n}$.

Properties:

- $\hat{D}_{\xi}^{\dagger}\hat{D}_{\xi} = \mathbb{1}$ (Unitary operator).
- $\bullet \ \hat{D}_{\xi}\hat{D}_{\xi} = \hat{D}_{2\xi}.$
- $\hat{D}_{\xi} + \hat{D}_{\eta} = e^{-\frac{i}{2}\xi^{T}\Omega\eta} \hat{D}_{\xi+\eta}$. (**Prove!**)
- $\hat{D}_{-\bar{\xi}}\hat{\mathbf{x}}\hat{D}_{\bar{\xi}} = \hat{\mathbf{x}} \bar{\xi} \; (\mathbf{Prove!})$
- $\bullet \ \hat{D}_{-\bar{\xi}} = \hat{D}_{\bar{\varepsilon}}^{\dagger}.$

Using the above fourth property we can write,

$$\hat{H}' = \frac{1}{2} (\hat{\mathbf{x}} - \bar{\xi})^T H (\hat{\mathbf{x}} - \bar{\xi}) = \frac{1}{2} (\hat{D}_{-\bar{\xi}} \hat{\mathbf{x}} \hat{D}_{\bar{\xi}})^T H (\hat{D}_{-\bar{\xi}} \hat{\mathbf{x}} \hat{D}_{\bar{\xi}})$$

$$1 \hat{\mathbf{x}} = T - \hat{\mathbf{x}} \hat{\mathbf{x}} \hat{D}_{\bar{\xi}}$$

$$(5)$$

$$= \frac{1}{2}\hat{D}_{-\bar{\xi}}\hat{\mathbf{x}}^T H \hat{\mathbf{x}} \hat{D}_{\bar{\xi}} \tag{6}$$

See Serafini (eq. 3.17) for proof.

2.3 Symplectic Group

 $\bf TODO:$ Linear canonical transformation and Symplectic group, Canonical transformations are those which respect $\bf CCR.$

Definition 3 (Symplectic group).

$$S \in Sp_{2n,\mathbb{R}} \iff S\Omega S^T = \Omega \tag{7}$$

2.4 Normal Modes

TODO: Definition, etc.
